

Computational Economics: Problem Set 4

Emma (Sunwoo) Cho

Question 1 & 2 & 5

- The code and explanations are in the .py file.

Question 3

Table 1: MLE estimates of the ln-wage model by year (male heads, age 25–60, wage > \$7/hr)

	1971	1980	1990	2000
Constant	0.5863	1.0023	0.2772	-0.2952
Educ	0.0665	0.0660	0.0955	0.1102
Age	0.0649	0.0456	0.0579	0.0845
Age ²	-0.0006	-0.0004	-0.0005	-0.0009
Black	-0.1641	-0.1030	-0.1680	-0.2598
Hispanic	0.0000	0.0000	0.0000	0.0000
OtherRace	0.0175	0.0123	-0.0520	-0.0622
$\hat{\sigma}$ (MLE)	0.4059	0.4478	0.4815	0.5342
Log-likelihood	-713.71	-1142.42	-1385.08	-2043.02
n	1380	1856	2013	2580

Estimates from $\ln w_{it} = \alpha + \beta_1 Educ_{it} + \beta_2 Age_{it} + \beta_3 Age_{it}^2 + \beta_4 Black_{it} + \beta_5 Hispanic_{it} + \beta_6 OtherRace_{it} + \varepsilon_{it}$.
White is the baseline (=1). Assumed the homoskedastic and normally distributed error term.

Question 4

Interpret β_1 (Educ), based on year-by-year estimates. How do the returns to education change over time in these data?

- **1971:** $\beta_1 = 0.0665, 100(e^{0.0665} - 1), \approx 6.9\%$, so each year of additional schooling increases the wage by approximately 6.9%.
- **1980:** $\beta_1 = 0.0660, \approx 6.8\%$ per year, so each year of additional schooling increases the wage by approximately 6.8%.
- **1990:** $\beta_1 = 0.0955, \approx 10.0\%$ per year, so each year of additional schooling increases the wage by approximately 10.0%.
- **2000:** $\beta_1 = 0.1102, \approx 11.7\%$ per year, so each year of additional schooling increases the wage by approximately 11.7%.
